# Chapter 1

## Methods

### 1.1 Data Download

Least Tern detection data was downloaded from Motus using the motus R package, and then filtered to remove false positive detections. Detailed information on data download processes, formats, and false detections can be found here: <https://motus.org/MotusRBook/>.

### 1.2 Data Cleaning

Strings of detections with only 2 consecutive detections at a station (run length = 2) are questionable and may indicate the tag was just barely within range of the station, or more likely, that it is a false positive produced by background radio noise which is present to varying degrees at all stations.

To begin, several tags were never detected near the breeding site and were removed (2017 Lotek tag ID's 95, 96, 97, 2018 Lotek tag ID 315). Then, detections at stations outside the tagging area with a run length of 2 were deemed to be false positives and removed. Each remaining tag was then visually inspected to examine detections that occurred at questionable latitudes far from the breeding site. Several stations had large numbers of detections with low run lengths, this is characteristic of stations with high levels of background radio noise which can often result in false positives. These stations were *Drasher*, *RTNJ*, *Koffler*, *Waggoners Gap*, *Burntpoint*, *Los Vientos Forest*, and *D'Estimaувille*. Further inspection of detections at these stations showed that it would be biologically impossible for birds to make the flights between detections on the breeding ground and subsequent detections at these stations in the amount of time between detections. Therefore, all detections at these stations were deemed to be false positives due to noisy sites.

Remaining detections far from the tagging location were examined, many had run lengths of only 2 which are questionable at best and were deemed to be false positives. Others with run lengths of 3 or 4 were not biologically possible flights such as between the tagging area and eastern Canada.

All detections deemed to be false positives were added to a custom filter that was applied to the data and were excluded from further analysis.

Detailed data filtering methodology with complete R code is available in Appendix A.

### 1.3 Data Manipulation

Detailed nest monitoring records were used to determine tag retention and incubation periods. To determine incubation period, each tag was assigned an end date based on recorded nest fate, once a nest's fate was

categorized as either “failed nest”, “successful nest”, or “eggs due to hatch but no chicks found”, it was assigned an end date of that day.

Lotek tag ID’s 114 and 316 did not have any nest records, as their incubation period could therefore not be determined, they were excluded from further analysis.

Several tags were only detected for a short period of time; for meaningful results, tags that were detected for less than 24 hours were excluded from further analysis (Lotek tag ID’s 85, 98, 120, 130, 286, 288, 309, 312). See table 1.1 for a detection summary of all tags during incubation.

Table 1.1: Incubation detection period for all tags

Year	motusTagID	mfgID	First Detection	Final Detection	Detection Period (days)	Number of Sites

## 1.4 Site Visits

To determine the frequency at which Least Terns visited each foraging area, detections at each station were grouped into distinct ‘visits’. A visit was categorized as a period of consecutive detections (in minutes) at a single station, or multiple periods of consecutive detections at a single station where there were fewer than 10 minutes between consecutive periods of detection. Detailed visit summaries are available in Appendix C.

For each year, an ANOVA test was initially used to determine if the length of visits differed between stations, results indicated that the mean time spent at stations differed significantly between stations for 2017 ( $p < 0.001$ ) and 2018 ( $p = 0.001$ ). A Tukey Test was then implemented to discern where the difference lay for both years.

## 1.5 Time Partitioning

To determine time partitioning between foraging activities and nest site attendance during the incubation period, individuals that were consistently detected at the nesting site (*Exxon Fields*) were selected. Detection patterns were visually inspected for all tags, and those that were not reliably detected at the nesting site were excluded. In total 5 and 7 tags were selected from 2017 and 2018 respectively. Periods of time during which it could not be confirmed that the bird was incubating were also excluded, for example, the nest of tag 282 was predated sometime between May 18-21st, and the detection pattern clearly changes during this time, thus detections beyond May 18th were removed for this bird, Figure 1.1 shows the detections used for time partitioning analysis.

To discern behavioural patterns during the incubation period, detections were examined at two levels using the same technique. First, all detections were examined to review general *colony* attendance. Second, only detections with a signal strength below 70 were examined as an indication of *nest* attendance, as periods of prolonged low signal strength generally indicate the individual is on the nest. In both cases, only detections at *Exxon Fields* were examined for this subset of tags.

For both levels, detection periods at *Exxon Fields* were split into discrete ‘visits’ in the same way site visits were determined; consecutive detections at *Exxon Fields*, or runs of consecutive detections with less than 10

minutes between runs, were classified as one ‘visit’. For nest attendance, visits with  $< 3$  detections were also excluded, as we would also expect short periods of decreasing signal strengths as the individual is flying away from the station to forage, as compared to prolonged periods of consistently low signal strength indicative of nest attendance. Furthermore, time of dawn and dusk was used to classify detections as occurring during the day or night.

An ANOVA was used to examine the effect of time of day (day or night) on signal strength and visit length during 2017 and 2018 for site attendance.

Figure 1.1: Signal strength vs. time at Exxon Fields for tags with reliable detections during incubation.

# Chapter 2

## Results

### 2.1 Study Area

Stations within the study region are presented in Figure 2.1, stations with red outlines had no detections, while coloured stations had at least one tag detected during the study period from 2017 to 2018. Triangles represent receivers that were active during 2017 *and* 2018, circles represent stations that were only active in 2017 (*Quintana* and *East Grand Terre*). The blue lines indicate the direction of antennas during the study period and span 15 miles from the receiver. All receivers maintained the same bearings throughout the study period with the exception of *Bolivar\_Flats*, here the solid blue lines are the 2017 bearings, while the dashed blue lines are the 2018 bearings.

All Least Terns were tagged within close proximity of *Exxon Fields*, and for the purposes of this report stations considered within proximity to the breeding area are *Exxon Fields*, *East Grand Terre*, *Grand\_Isle*, and *Wisner*. A close up of this area is presented in the inset of Figure 2.1.

### 2.2 Detection Overview

In 2017, only one individual (tag ID 136) was detected at stations outside the immediate tagging region, all other individuals and the bulk of the detections occurred at *Exxon Fields*, *East Grand Terre*, *Grand\_Isle*, and *Wisner*. Figure 2.2 shows a map of all 2017 tagged bird detections, lines are coloured by tag ID. Figure 2.3 displays the same data by plotting latitude vs. time for each tag, with points coloured by receiver site.

In 2018, again only one individual was detected outside the immediate tagging region (tag ID 283), all other individuals and the bulk of the detections occurred at *Exxon Fields*, *East Grand Terre*, and *Grand\_Isle*. Note that in 2018 no birds were detected at *Wisner* despite close proximity to nesting areas. Based on receiver performance outputs, this is likely due to receiver functionality rather than a true lack of detections. Figure 2.4 shows a map of detection pattern of all 2018 tagged birds, while Figure 2.5 displays the same data as individual tag plots of latitude vs. time.

### 2.3 Foraging vs Incubating

Figure 2.6 is a selection of 4 representative detection patterns of individuals; examining the signal strength it is not always clear when birds are attending the nest site and when they are foraging. For example, tag 94 shows clear daily signal strength patterns, with low signal strength occurring overnight when the bird is likely incubating. Tag 93 has a similar but less distinct pattern; some nights the bird is detected while other nights it is not. In other cases the tag is picked up far less consistently as in tag 303, and in even more

Figure 2.1: Map of study region during 2017 and 2018. Triangles represent receivers that were active during 2017 and 2018, circles represent stations that were only active in 2017. Stations outlined in a red circle had no detections while coloured stations had at least one detection during the study period. Blue lines indicate antenna bearings spanning 15 miles from the station, bearings remained constant throughout the study period with the exception of *Bolivar\_Flats* where the solid lines indicate 2017 bearings and dashed lines indicate 2018 bearings.

Figure 2.2: Map of 2017 tag detections, only tag 136 was detected outside the immediate tagging region.

extreme cases as in tag 289 For these final two tags, the bird is rarely if ever detected while incubating, and most detections likely occur as the bird is leaving or arriving at the nest site.

Furthermore, even tags with clear daily detection patterns as in tag 94, shorter nest site attendance periods during the day are not as obviously picked up. However, based on these detections, the signal strength during incubation is generally much lower than during flight. This is to be expected as a tags detection range increases substantially when a bird is in the air as compared to on the ground (low signal strength = weaker detection). Therefore, all detections on the Exxon Fields receiver with a signal strength < 70 will be excluded from foraging analysis from this point forward to exclude likely detections on the nest during incubation. While this will invariably also remove detections on Exxon Fields that may occur when the bird is in flight, since the station is in very close proximity to the nesting site, in most cases this will only remove the tail ends of a detection streak as the bird is departing or approaching the nesting site.

## 2.4 Heavily Frequented Foraging Areas

To add meaning to receiver detections, the distance from *Exxon Fields* was calculated for each station where tags were detected and are presented in table 2.1. A full database with distances calculated between all stations can be found in Appendix B.

Table 2.1: Distance in miles between each receiver and Exxon Fields

Site Name	Distance from Exxon Fields (mi)
Exxon Fields	0
Grand_Isle	1.967
East Grand Terre	7.848
Wisner	14.34
Rock W	175
Sabine NWR	211.1
High_Island	267.2
Bolivar_Flats	288.4
Scenic Galveston	298.4

Site Name	Distance from Exxon Fields (mi)
Brazoria National Wildlife Refuge	320.9
Quintana	323.5
San Bernard National Wildlife Refuge Headquarters	339.8
San Bernard NWR (Big Pond Unit)	353.6
Rockport Bay Education Center	437.9

For each station the total number of visits was calculated (Figure 2.7), as expected *Exxon Fields* had by far the highest number of visits as it was at the nesting area. In 2017 and 2018 *Grand Isle* had the next highest frequency of detections, this is not surprising as it is the closest station to the nesting area (see table 2.1). *East Grand Terre* and *Wisner* followed with lower numbers of site visits and are also near the nesting area. Note the lack of detections at *Wisner* in 2018, this is likely due to receiver malfunction rather than a true lack of detections. All other stations had negligible (<3) visits and are substantially farther away from the nesting grounds.

The length of visits was consistent with the number of visits, that is, birds generally had longer detection periods at *Exxon Fields*, followed by *East Grand Terre*, *Grand Isle*, and *Wisner*. However, for both 2017 and 2018 only *Grand Isle* and *Exxon Fields* differed significantly ( $p < 0.001$ ) in their visit length. Figure 2.8 shows the mean length of time each bird was detected at each station during each visit (See Appendix C for complete visit information).

Of the birds that were detected at *Exxon Fields* in 2017 and 2018, all were detected on at least 6 different visits. At *Grand Isle*, the majority (39/44, 88.6%) of birds were detected on more than 2 separate occasions ( $>2$  discrete visits). In comparison, at the remaining stations less than half (10/23, 43.5%) were detected on more than two occasions. Only tag 23261 appeared semi-regularly at *Wisner* but is notable in 12 detections.

Thus birds appear to spend the majority of their time in close proximity to *Exxon Fields*, however this could be a by-product of increased detection due to proximity to nesting sites and therefore a necessity to frequently pass the receiver regardless if foraging is occurring nearby or not. Most birds frequented *Grand Isle* regularly which could be due to nearby foraging, or a proximity to the nesting site.

#### 2.4.1 Simultaneous Detections

If stations are within close proximity of one another, it's possible to get simultaneous detections on both stations at once. During incubation there were 208 pairs of simultaneous detections, 2 of these occurred between *East Grand Terre* and *Exxon Fields*, 3 between *East Grand Terre* and *Grand Isle*, and the other 203 between *Exxon Fields* and *Grand Isle*. *Exxon Fields* and *Grand Isle* are the closest two stations at 1.97 miles apart, easily within range of each other particularly when birds are in flight (see Appendix B). *East Grand Terre* is 7.85 miles and 9.80 miles away from *Exxon Fields* and *Grand Isle* respectively, the next closest pairs of stations.

#### 2.4.2 Detection Directions

We can narrow down the areas visited beyond which site they were detected at by examining which antenna they were detected on during foraging. Figures 2.9 and 2.10 show the total number of detections for each antenna bearing at each site for 2017 and 2018 respectively, while figures 2.11 and 2.12 show the total number of birds and cumulative detection time of each antenna at each site for 2017 and 2018 respectively.

Detection patterns are similar at *Exxon Fields*, *Grand Isle*, and *East Grand Terre* in 2017 and 2018. Detections at *Exxon Fields* were predominantly to the SW, directly in line with the tagging area, this also indicates that birds likely arrive and depart to/from the nesting location from the SW. *Grand Isle* detections were overwhelmingly more prevalent to the NE, pointing towards the nearby colony, while this may indicate

Figure 2.3: Individual 2017 plots by Motus tag ID showing latitudinal movements of tags over time, detection points are coloured by station location. Note that the x and y scales vary between tag plots.

Figure 2.4: Map of 2018 tag detections, only tag 283 was detected outside the immediate tagging region.

that birds don't spend much time foraging to the SW, it could also be due to the sheer proximity of the nesting site. As discussed earlier, nearly all cases of simultaneous detections between two stations occur between *Exxon Fields* and *Grand Isle*, suggesting that many of the arrival and departure flights from the colony could be captured by both stations, resulting in the high number of NE detections at *Grand Isle* being an artifact of colony attendance. *East Grand Terre* had the most detections by far to the SW, again towards the colony.

Both the number of detections and the cumulative detection time was highest at *Exxon Fields* in both years, followed by *Grand Isle* and then *East Grand Terre*. All 21 individuals with foraging detections in 2017 were detected by both *Exxon Fields* and *Grand Isle*, while in 2018 all 24 foraging individuals were detected at *Exxon Fields*, only 23 were detected at *Grand Isle*. The cumulative detection time at *Grand Isle* is also markedly shorter than at *Exxon Fields* in 2018. In both years, smaller numbers of birds and shorter cumulative detection times occurred at *East Grand Terre*, and even fewer at *Wisner* (as noted previously, a lack of 2018 detections at *Wisner* is likely due to receiver malfunction rather than true lack of tags in the area).

In 2017, birds were picked up in very small numbers outside of the immediate breeding area. It is difficult to make generalized assumptions from such a small number of detections, however it does seem as though a few birds may be using the areas off the coast around *Quintana*. There are even fewer detections away from the colony during incubation in 2018, but those that do occur are in the same region.

## 2.5 Mean Distances Travelled for Foraging

Based on detection data, in 2017 the mean distance travelled for all detection periods was 1.47 miles ( $SE = 0.38$ ), with a maximum distance travelled to *San Bernard NWR (Big Pond Unit)* at 353.62 miles. In 2018 the mean distance travelled was 0.50 miles ( $SE = 0.12$ ), with a maximum distance travelled of 288.39 miles to *Bolivar Flats*. However, the vast majority of detections (4,670/4,678 or 99.8%) during foraging trips occurred within 14.34 miles from the colony detected at the four closest receiver stations (*Exxon Fields*, *Grand Isle*, *East Grand Terre*, and *Wisner*).

Figure 2.5: Individual 2018 plots by tag ID showing latitudinal movements of tags over time, detection points are coloured by station location. Note that the x and y scales vary between tag plots.

Figure 2.6: Signal strength vs. time of four representative tags at select periods of incubation. Points represent individual detections coloured by Receiver, vertical blue lines indicate dusk, and vertical orange lines indicate dawn. A higher signal strength correlates to a stronger detection. Note x and y scales vary between plots.

Figure 2.7: Detection frequencies of tags at each station by year, ordered by distance from *Exxon Fields*

## 2.6 Time Partitioning Between Foraging and Nest Site Attendance

Only tags detected reliably during incubation at Exxon Fields were used for the following analysis, this included 5 tags from 2017, and 7 tags from 2018. In addition, only detections at Exxon Fields are used in this section.

Colony site (*Exxon Fields*) detection plots in figures 2.13 and 2.14 show a clear difference between nocturnal and diurnal behaviours reflected in detection patterns. Nocturnal site visits were on average 30.41 (SE = 4.33) and 16.83 (SE = 1.88) minutes for 2017 and 2018 respectively, while detections during the day were 12.85 (SE = 0.81) and 10.73 (SE = 0.57) minutes for 2017 and 2018 respectively, mean detection length was significantly different ( $p < 0.001$ ) for both years (table 2.2). Signal strength was also significantly different ( $p < 0.001$ ) between nocturnal and diurnal detections in both years. Mean signal strength for each visit was 65.62 (SE = 1.12) and 59.01 (SE = 1.17) during the night compared 89.84 (SE = 0.73) and 73.58 (SE = 0.84) during the day for 2017 and 2018 respectively. This indicates important daily differences in Least Tern behaviour, during the night birds are likely to be on the nest resulting in prolonged periods of detections with low signal strength, however during the day as the birds are travelling to and from the nest while foraging, they have shorter periods of nest attendance and higher signal strengths as birds in the air are more readily detected.

Table 2.2: Mean length and signal strength of visits during 2017 and 2018 split by day vs. night detections (continued below)

Year	Period	Mean length of detection periods (mins)	Standard error of detection periods
2017	day	12.85	0.81

Year	Period	Mean length of detection periods (mins)	Standard error of detection periods
2017	night	30.41	4.33
2018	day	10.73	0.57
2018	night	16.83	1.88

Mean signal strength of detections	Standard error signal strength
89.84	0.73
65.62	1.12
73.58	0.84
59.01	1.17

During daylight hours (between dawn and dusk) when Least Terns are actively foraging, they were detected by Exxon Fields on average 22.22% and 16.19% of the time in 2017 and 2018 respectively. As these tags were already screened as tags that are reliably detected during nest attendance, this suggests that during the day the majority of the birds time is spent away from the nest.

By filtering detections even further, and only examining visits that were below the signal strength threshold of 70 with at least 3 detections, we can discern *nest* attendance. Least Terns had a mean visit length of 13.88 (SE = 1.28) and 13.42 (SE = 0.75) minutes, and on average had 6.7 (SE = 0.79) and 7.3 (SE = 0.62) visits to the nest during daylight hours in 2017 and 2018 respectively. Note that this should be treated as anecdotal information due to the small sample size.

Table 2.4: Mean length and number of daylight nest attendance (signal strength < 70 for visits with at least 3 detections) during 2017 and 2018 (continued below)

Year	Mean length of detection periods (mins)	Standard error detection periods
2017	13.88	1.28
2018	13.43	0.75

Mean number of daily visits	Standard error number of daily visits
6.71	0.79
7.333	0.62

Figure 2.8: Mean length of foraging visits in minutes at each station for 2017 and 2018, ordered by distance from Exxon Fields. Note that the plot has been cut off due to the high number of outliers, *Exxon Fields* had a maximum visit length of 61 minutes, *Grand Isle* 107 minutes, *East Grand Terre* 19 minutes, *Wisner* 27 minutes.

Figure 2.9: Frequency of all 2017 foraging detections on each antenna. Increasingly darker blue bars indicate increased numbers of detections during the incubation period, orange lines indicate antenna bearings at each site. Note that scales differ by site.

Figure 2.10: Frequency of all 2018 foraging detections on each antenna. Increasingly darker blue bars indicate increased numbers of detections during the incubation period, orange lines indicate antenna bearings at each site. Note that scales differ by site.

Figure 2.11: Cumulative 2017 detections of 21 foraging birds by each antenna at the colony site. Solid Blue lines indicate antenna bearings extending outward 10km from the receiver, numbers associated with each antenna indicate the number of tags detected, and the circles surrounding each number are coloured by cumulative detection time.

Figure 2.12: Cumulative 2018 detections of 24 foraging birds by each antenna at the colony site. Solid Blue lines indicate antenna bearings extending outward 10km from the receiver, numbers associated with each antenna indicate the number of tags detected, and the circles surrounding each number are coloured by cumulative detection time.

Figure 2.13: Signal strength vs. time of 2017 tag detections during incubation at nesting site (Exxon Fields), each plot is one individual, red points are detections during the day, and blue points are detections during the night. Orange and blue vertical lines indicate dawn and dusk respectively.

Figure 2.14: Signal strength vs. time of 2018 tag detections during incubation at nesting site (Exxon Fields), each plot is one individual, red points are detections during the day, and blue points are detections during the night. Orange and blue vertical lines indicate dawn and dusk respectively.

# Chapter 3

## Conclusions

### 3.1 Heavily Frequented Foraging Areas

Foraging detections of Least Terns during 2017 and 2018 were concentrated around the colony/tagging area. In both years only one tag was detected outside the immediate tagging area (near the *Quintana* station), while the bulk of foraging visits (both in terms of number of detections and cumulative detection time) occurred at *Exxon Fields*, *Grand\_Isle* and *East Grand Terre* in order of decreasing frequency. There were also notable but smaller numbers of detections at *Wisner* in 2017 but not 2018, however this is likely due to receiver malfunction rather than a lack of tag presence near the station. In general, the majority of detections at these stations were on antennas pointing towards the tagging area. *Exxon Fields* had predominately SW detections, while *Grand\_Isle* had detections primarily by the NE antennas.

Length of foraging visit followed the same pattern, that is visits were longest at *Exxon Fields*, followed by *East Grand Terre*, *Grand\_Isle* and *Wisner*; only *Exxon Fields* and *Grand\_Isle* differed significantly in foraging visit length.

### 3.2 Mean Distances Travelled for Foraging

Mean distance travelled in 2017 and 2018 was 1.47 miles and 0.50 miles respectively. While the maximum distances travelled in each year was 353.62 and 288.39 miles, the vast majority of foraging detections occurred within 14.34 miles of the colony.

### 3.3 Time Partitioning Between Foraging and Nest Site Attendance

Due to the limited number of birds consistently detected while on the nest (5 in 2017 and 7 in 2018), the following conclusions should be taken as anecdotal information.

Time partitioning between foraging and colony site attendance at *Exxon Fields* differed between nocturnal vs diurnal detections with the latter being nearly half as long. Signal strength was also significantly lower during nocturnal detections for both years. Together this indicates daily differences in behaviour, it is likely that during the nights birds are spending longer periods on the nest resulting in prolonged periods of low signal strength, compared to the day where nest site attendance periods are short with potentially more movement resulting in higher overall signal strengths at *Exxon Fields*. Further to this point, Least Terns were

detected by the colony receiver between 16-22% of the time during the day when they are actively foraging, indicating that birds spend the majority of their time away from their nests.

Assuming that birds are on their nests when there is a prolonged signal strength below 70, it appears that Least Terns spend on average 14 minutes at the nest during daylight nest attendance periods.

Finally, while it appears that birds spend the majority of their time in close proximity to *Exxon Fields*, it is important to note that this may be a function of birds being obligated to return to their nest site, nor does it preclude other important foraging areas that may be out of range of the current receiver station setup.

# **Chapter 4**

## **Recommendations**

Further study is recommended to determine key foraging areas and obtain larger sample sizes to analyze nest site attendance. Increasing the density of shoreline stations throughout the region could highlight currently unknown key foraging areas along the coast, or alternatively, could indicate the Least Terns are foraging either within close proximity to the colony, or farther offshore than stations can detect. Setting up a smaller omni directional antenna within the colony could provide more robust detections of birds while on the nest. This, coupled with some level of manual tracking to confirm the assumptions made in this report regarding nest site attendance could further our knowledge of the spatial and temporal requirements of breeding Least Terns.

# Appendix A

## Appendix - Downloading and Cleaning Data

Detailed instructions for accessing and understanding data can be found in the Motus R Book, available [here](#).

### A.1 Loading Packages

In order to download data and complete the analysis you will need a number of packages, if you do not already have them installed, follow the instructions below:

```
# Install devtools to allow download of Motus R
# packages
install.packages("devtools")

# Install motus for data download, data
# manipulation, visualization and analysis
install_github("MotusWTS/motus")

# install motusClient for data download
install_github("MotusWTS/motusClient")

# install packages for analysis
install.packages("ggmap")
install.packages("tidyverse")
install.packages("gridExtra")
install.packages("ggplot2")
install.packages("viridis")
install.packages("knitr")
install.packages("pander")
```

Once packages are installed, load them into your project. To download and filter the data we will only need use of the motus R package which is loaded with the ‘library’ function:

```
# load motus package
library(motus)
```

## A.2 Data Download - project 132

Downloading data from Motus requires you to enter your Motus username and password, you will only have access to data for projects to which you are registered. To register with Motus visit <https://motus.org/>.

To download data for the **first time** to your working directory:

```
proj.num <- 132 # assign the correct project number
sql.motus <- tagme(projRecv = proj.num, new = TRUE,
                    update = TRUE)
```

To update an existing sql.motus file to your working directory:

```
proj.num <- 132 # assign the correct project number
sql.motus <- tagme(projRecv = proj.num, new = FALSE,
                    update = TRUE)
```

## A.3 Accessing Data

Data is downloaded as an SQL file, to analyze data the SQL file is converted into a flat file and only relevant columns and Least Tern tags are retained. At the same time a new column for receiver latitude and longitude is created, consisting of the GPS latitude if available, infilled with the deployment latitude if GPS is not available.

```
tbl.alltags <- tbl(sql.motus, "alltags") # convert sql file to a tbl
df.alltags <-tbl.alltags %>%
  mutate(recvLat = if_else(is.na(gpsLat) | gpsLat == 0), # create new lat/lion variables
        recvDeployLat, gpsLat),
  recvLon = if_else(is.na(gpsLon) | gpsLon == 0),
        recvDeployLon, gpsLon)) %>%
  #remove unnecessary columns
  select(-ambigID, -tagProjID, -sigsd, -noise, -freq, -freqsd, -slop, -burstSlop,
         -done, -bootnum, -tagType, -codeSet, -mfg, -tagModel, -tagLifespan,
         -nomFreq, -pulseLen, -markerNumber, -markerType, -tagDeployAlt,
         -tagDeployComments, -fullID, -recvDeployAlt, -antHeight, -speciesFR,
         -speciesSci, -speciesGroup, -tagProjName, gpsAlt, recvSiteName) %>%
  filter(speciesEN == "Least Tern") %>% # keep only LETE
  collect() %>%
  as.data.frame %>% # convert tbl to data.frame
  # convert times to datetime
  mutate(ts = as_datetime(ts, tz = "UTC", origin = "1970-01-01"),
         tagDeployStart = as_datetime(tagDeployStart, tz = "UTC", origin = "1970-01-01"),
         tagDeployEnd = as_datetime(tagDeployEnd, tz = "UTC", origin = "1970-01-01"))
```

## A.4 Dataframe of motusTagID and Lotek tag ID

```
tagIDs <- unique(select(df.alltags, motusTagID, mfgID))
```

## A.5 Cleaning Data

Projects with receivers in the tagging area are 31, 65, 120, and 132, initially all detections from receivers registered to these projects will be retained. For all other projects any detections with a runLen < 2 are deemed to be false positives. Filter ‘blocks’ are created each time a detection is identified as a false positive, at the end of the cleaning process all the false positive blocks are combined to create a single filter to apply to all the data.

First, remove detections outside tagging area with a runLen of 2:

```
# create list of projects with receivers outside the tagging area
nonTaggingLocs <- unique(filter(df.alltags,
                                    !(recvProjID %in% c(31, 65, 120, 132)))$recvProjID)
lete17 <- filter(df.alltags, year(ts) == 2017, # filter to only 2017 detections
                  !(recvProjID %in% nonTaggingLocs & runLen == 2)) %>%
# remove detections with a runLen <= 2 for stations outside tagging area
arrange(motusTagID, ts)

# create the first filter block
df.block.0 <- filter(df.alltags, year(ts) == 2017,
                      recvProjID %in% nonTaggingLocs & runLen == 2)
```

Next, detections are plotted by latitude to visually identify other questionable detections to eventually create more blocks of false positives for the final filter. Below are detections for all 2017 tags by latitude:

Tags are removed that were never detected at the breeding site, these are **23220**, **23221**, and **23222**.

```
# remove tags 23220, 23221, 23222 and create a
# block
lete17 <- filter(lete17, !(motusTagID %in% c(23220,
  23221, 23222)))
df.block.1 <- filter(df.alltags, year(ts) == 2017 &
  motusTagID %in% c(23220, 23221, 23222))
```

Next, tags that were detected outside the breeding area are examined: **23212**, **23214**, **23216**, **23219**, **23223**, **23225**, **23226**, **23227**, **23270**. Below is a plot of these tags, and a table displaying the number of runs with runLen < 5 for each station:

	recvDeployName	runLen	n
## 1	Bolivar_Flats	2	2
## 2	Peveto Woods	2	2
## 3	San Bernard National Wildlife Refuge Headquarters	2	2
## 4	Sabine NWR	2	4
## 5	Rockport Bay Education Center	2	6
## 6	High_Island	2	8
## 7	Wisner	2	8
## 8	Scenic Galveston	2	24
## 9	Quintana	2	28
## 10	San Bernard NWR (Big Pond Unit)	2	30
## 11	Grand_Isle	2	82
## 12	Exxon Fields	2	4688
## 13	RTNJ	3	3
## 14	Swallowtail	3	3

```

## 15 Drasher      3   9
## 16 Wisner       3  12
## 17 Waggoners Gap 3   60
## 18 Koffler        3  72
## 19 Grand_Isle    3 120
## 20 Burntpoint    3 258
## 21 Los Vientos Forest 3 411
## 22 Exxon Fields   3 5736
## 23 Koffler        4   12
## 24 Waggoners Gap   4   12
## 25 Los Vientos Forest 4   32
## 26 Grand_Isle     4   72
## 27 Exxon Fields   4 4952

```

Stations that stand out as having a large number of runLen = 3, far outside the tagging area include: *Koffler*, *Waggoners Gap*, *Burntpoint*, and *Los Vientos Forest*. These are likely sites with a large amount of background radio noise leading to increased levels of false positives. To confirm, a few examples are provided below.

For tag **23216**, given the amount of time and distance between detections at *RTNJ* and *Exxon Fields*, and between *Koffler* and *Exxon Fields*, these are not biologically possible flights and these detections will be removed:

For tag **23270**, it again appears there are clear false positives that can be removed at *Koffler*, *Los Vientos Forest*, *Drasher*, and *Waggoners Gap*. These detections will therefore be flagged as false positives:

Create a filter block to remove noisy sites with high amounts of short runLen's:

```
df.block.2 <- filter(df.alltags, year(ts) == 2017,
  recvDeployName %in% c("Drasher", "RTNJ", "Koffler",
  "Waggoners Gap", "Burntpoint", "Los Vientos Forest"))
```

Removing the sites with a high number of low runLen's (*Drasher*, *RTNJ*, *Koffler*, *Waggoners Gap*, *Burntpoint*, *Los Vientos Forest*) results in much cleaner plots:

There are three remaining tags with questionable detections: **23219**, **23225**, **23227**:

To determine if detections are reliable, each tag will be examined on an individual basis.

**Tag 23219:** Detections at Rockport Bay Education Center are only runLen 2, these are not reliable detections.

**Tag 23225:** detections at Peveto Woods are only runLen 2, these are not reliable detections:

**Tag 23227:** all detections after June 15 are of runLen 2, except for detections at Swallowtail (receiver latitude = 45, runLen = 3) which are too far away to be legitimate detections so these will be removed.

A filter block is created to remove false detections for the three tags above:

```
df.block.3 <- filter(df.alltags, year(ts) == 2017,
  motusTagID == 23219 & recvDeployName == "Rockport Bay Education Center")
df.block.4 <- filter(df.alltags, year(ts) == 2017,
  motusTagID == 23225 & recvDeployName == "Peveto Woods")
df.block.5 <- filter(df.alltags, year(ts) == 2017,
  motusTagID == 23227 & ts > as.POSIXct("2017-06-15"))
```

The process is repeated with 2018 detection data, starting by removing detections from stations outside the tagging area with a runLen < 2:

```
# create list of projects with receivers outside the tagging area
lete18 <- filter(df.alltags, year(ts) == 2018, # filter to only 2018 detections
  !(recvProjID %in% nonTaggingLocs & runLen == 2)) %>%
# remove detections with a runLen < 2 for stations outside tagging area
  arrange(motusTagID, ts)
# create the first filter block
df.block.6 <- filter(df.alltags, year(ts) == 2018,
  recvProjID %in% nonTaggingLocs & runLen == 2)
```

Next, all tags are plotted by latitude to visually identify potential false positives.

Plot of all 2018 tags by latitude:

Tags that were never detected at the breeding site are removed and a filter block is created: **28614**

```
lete18 <- filter(lete18, !(motusTagID == 28614))
df.block.7 <- filter(df.alltags, year(ts) == 2018,
  motusTagID == 28614)
```

Next tags that were detected outside breeding area were examined: **28520, 28524, 28525, 28531, 28594, 28600**

Again, runLen for these detections is examined:

```
filter(lete18, motusTagID %in% c(28520, 28524, 28525,
  28531, 28594, 28600), runLen < 5) %>% group_by(recvDeployName,
  runLen) %>% summarize(n = length(motusTagID)) %>%
  as.data.frame() %>% arrange(runLen, n)
```

	recvDeployName	runLen	n
## 1	San Bernard National Wildlife Refuge Headquarters	2	2
## 2	Trinity River NWR Die House	2	2
## 3	Bolivar_Flats	2	4
## 4	East Grand Terre	2	6
## 5	San Bernard NWR (Big Pond Unit)	2	14
## 6	Brazoria National Wildlife Refuge	2	18
## 7	Grand_Isle	2	82
## 8	Exxon Fields	2	3174
## 9	BPLH	3	3
## 10	Curries	3	3
## 11	Drasher	3	3
## 12	Stutchbury	3	3
## 13	Old Cut	3	6
## 14	Koffler	3	12
## 15	Grand_Isle	3	48
## 16	D'Estimauville	3	159
## 17	Exxon Fields	3	2391
## 18	Koffler	4	8
## 19	D'Estimauville	4	20
## 20	Grand_Isle	4	32
## 21	Exxon Fields	4	1592

Stations that stand out as having a large number of runLen = 3, far outside the tagging area include: *D'Estimauville*, and as in 2017 *Koffler*. These are likely sites with a large amount of background radio noise leading to increased levels of false positives. Tags detected at these stations are examined individually to remove false positives.

**Tag 28520:** The detections at *D'Estimauville* in Quebec are not biologically possible given the timing, and was also flagged as a noisy site, these detections are flagged as false positives.

**Tag 28524:** Given the amount of time and distance between detections at *Koffler* and *Exxon Fields*, and between *D'Estimauville* and *Exxon Fields*, these are not biologically possible flights, they were also flagged as noisy stations. The detections at Stutchbury and Curries are of runLen 3, and occur in Ontario and Pennsylvania respectively. These detections are therefore flagged as false positives.

**Tag 28525:** Just as with tag 28520, the detection at *D'Estimauville* will be removed.

**Tag 28531:** Again, it is unlikely that this tag was in Ontario and Quebec in June so detections at *Koffler*, *Old Cut*, and *D'Estimauville* will be removed.

**Tag 28594:** Again, it is unlikely that this tag was in Nova Scotia, Ontario, or Pennsylvania (stations *BPLH*, *Old Cut*, and *Drasher* respectively), and all runLen are 3, so detections at these stations will be removed.

**Tag 28600:** Detections at *Koffler* and *D'Estimauville* once again appear problematic and will be removed.

Since all false positives in these cases are for the same stations, one filter block is used to apply to these false detections:

```
df.block.8 <- filter(df.alltags, year(ts) == 2018,
  recvDeployName %in% c("D'Estimauville", "Koffler",
  "Stutchbury", "Curries", "Old Cut", "BPLH",
  "Drasher"))
```

Here the plots are redone after removing the above identified false positives:

Now that filter blocks have been created for all false positives, a single custom filter is created for all false positives. The Motus R package offers functionalities to save your filters directly within your .motus file. Once they're saved in your database, you can do the type of left\_join as below without having to rely on data frames or an RDS file to store your data. More info can be found in Appendix D of the Motus R Book.

```
# Combine our df.blocks into a single data frame,
# and apply a probability of 0 for filtered
# records.
df.block.all <- bind_rows(df.block.0, df.block.1, df.block.2,
  df.block.3, df.block.4, df.block.5, df.block.6,
  df.block.7, df.block.8) %>% mutate(probability = 0)

# Create a new filter with the name filtFalsePos
# and populate it with df.block.all
tbl.filter = writeRunsFilter(sql.motus, "filtFalsePos",
  df = df.block.all, delete = TRUE)

# Obtain a table object where the filtered records
# from tbl.filter have been removed
tbl.alltags.sub <- left_join(tbl.alltags, tbl.filter,
  by = c("runID", "motusTagID")) %>% mutate(probability = ifelse(is.na(probability),
  1, probability)) %>% filter(probability > 0)
```

## Appendix B

# Appendix - Distances Between Receivers

The following table lists the latitude and longitude for each pair of receivers (X and Y), and distance (miles) between them:

Table B.1: Location and distance between each pair of receivers

Receiver X	Receiver Y	Location X	Location Y	Distance (mi)
Bolivar_Flats	Bolivar_Flats	29.37, -94.75	29.37, -94.75	0
Bolivar_Flats	Brazoria National Wildlife Refuge	29.37, -94.75	29.09, -95.28	37.3
Bolivar_Flats	East Grand Terre	29.37, -94.75	29.31, -89.86	294.9
Bolivar_Flats	Exxon Fields	29.37, -94.75	29.25, -89.97	288.4
Bolivar_Flats	Grand_Isle	29.37, -94.75	29.24, -90	286.6
Bolivar_Flats	High_Island	29.37, -94.75	29.56, -94.39	25.32
Bolivar_Flats	Quintana	29.37, -94.75	28.93, -95.31	45.29
Bolivar_Flats	Rock W	29.37, -94.75	29.71, -92.83	117.8
Bolivar_Flats	Rockport Bay Education Center	29.37, -94.75	28.03, -97.05	167.4
Bolivar_Flats	Sabine NWR	29.37, -94.75	29.89, -93.4	88.58
Bolivar_Flats	San Bernard National Wildlife Refuge Headquarters	29.37, -94.75	28.91, -95.58	59.23

# Appendix C

## Appendix - Site Visits

The following tables provide information on site visits to varying degree. Table C.1 includes the time and length of each visit for each tag. Table C.2 includes the total number and mean length of visits for each tag at each station. Table C.3 includes the total number and mean length of visits by station.

### C.1 Unique Visits

The following table shows the length in minutes of each unique visit:

Table C.1: Time and length of each unique visit for each tag

Motus Tag ID	Lotek ID	Receiver	Location	Distance from Exxon Fields (m)	First Detection	Final Detection	Visit Length (mins)

## C.2 Visits by tag and station

For each year and tag, the following table shows the total number and mean length (mins) of visits at each station:

Table C.2: Total number and mean length of visits (mins) for each tag by receiver

Year	Motus Tag ID	Lotek ID	Receiver	Total Number of Visits	Mean Length of Visits (mins)	Standard Error Visits
2017	23209	84	Exxon Fields	6	6.21	2
2017	23209	84	Grand_Isle	3	1.13	0
2017	23212	87	Exxon Fields	37	3.95	1
2017	23212	87	Grand_Isle	7	0.56	0
2017	23214	89	Exxon Fields	122	2.98	0
2017	23214	89	Grand_Isle	25	1.6	0
